Psychological flexibility: a new model of acceptance and commitment therapy. Despite the growing popularity of acceptance and commitment therapy (ACT), conceptual clarity has been limited. The aim of this paper is to provide a brief yet comprehensive review of psychological flexibility, from its origins to recent work with ACT, and its implications for the use of ACT and its application to traditional psychological interventions.

The review introduces the basic principles of ACT, psychological flexibility, and experiential avoidance and describes how ACT can be applied to common problems including pain, anxiety, depression, and life stress. Psychological flexibility is related to ACT, but it is also distinct and independent from ACT, as the theoretical basis of ACT focuses on acceptance, and the commitment to change that is typically associated with psychological flexibility is considered an outcome rather than a core treatment process. Psychological flexibility provides a useful conceptual framework for understanding the process of change in ACT. Gravity Probe In 1959, NASA launched a spacecraft called Explorer to space and let it fall. That's right, it fell. The spacecraft was so delicate that the slightest disturbance could change its orbit, and NASA did not want to risk it. So, the engineers built an arm of a telescope that could point at the moon, and the spacecraft would fall onto it, with a telemetry beacon that would ring until the arm touched the moon. Once the moon was close enough, the spacecraft would jettison the arm and float freely through space. But there was still the chance that the arm could hit another object, such as an asteroid. This would change the trajectory of the spacecraft, endangering the whole mission. NASA had an answer for this. If the spacecraft hit something, the arm would fly back to the moon and take a second picture. If the arm saw the same thing, this would mean that it had hit the same object, and the spacecraft would re-enter Earth's atmosphere in a controlled manner. They were right to build it this way. During its entire mission, the spacecraft only hit one object, something called Lunar Orbiter 1, which wasn't really a thing. (It was part of a pair of similar spacecraft, called Lunar Orbiter 2 and 3 82157476af
